Decorated Graphene Model 1

Following the 2018 discovery of superconductivity in twisted bilayer Graphene [1], graphene-based systems gained a renewed interest as a platform for strongly correlated physics. Two methods to engineer strong electron correlations emerged: twisted multilayer systems [1–5] and multilayer systems without twisting, such as Bernal bilayer, ABC or ABCA layered systems [6]. Through different means, electrons in these systems become localized so that interaction effects get more strongly pronounced. Connecting both kind of systems is the strong quantum geometry coming from the Graphene Dirac cones [7], which plays a role in stabilizing superconducting [2, 8] and magnetic order [9, 10].

Witt et al. suggested another platform for strongly correlated physics based on Graphene with the same strong quantum geometry, but higher intrinsic energy scales and thus also higher critical temperatures for strong correlation phenomena [11]. The model is inspired by an earlier experiment [12] of a SiC(0001) substrate with a single layer of Graphene on top and Sn as an intercalant[1] between the substrate and the Graphene layer. The system shows signs of Mott-Hubbard bands, a hallmark of strong correlation physics. Witt et al. suggested that by using different group-IV intercalants (C, Si, Ge, Sn, Pb) between the graphene sheet and the semiconducting SiC(0001) substrate, different distances to the Graphene sheet occur in the ground state. Band structures obtained from Density Functional Theory (DFT) show a relatively flat band at the Fermi level from the intercalant's p_z orbitals hybridized to the Dirac bands of graphene for all intercalants, with the hybridization strength being tuned by the equilibrium distance of the Graphene sheet and the intercalants.

In this thesis I will be treating an elemental model introduced in the work by Witt et al. capturing the essential flat band character of the system. The lattice structure can be seen in fig. 1.1. It consists of the usual hexagonal Graphene lattice, with an additional atom at one of the sublattice sites providing the flat band. Here, the hopping V models the hybridization

This elemental model shows two symmetry distinct Mott states for the small and large V regimes: in the low V regime, the X are responsible for the de-

[1] An intercalant is an atom or molecule inserted between the layers of layered system.

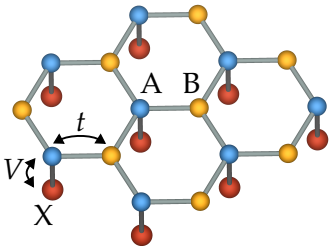

Figure 1.1 – Lattice structure of decorated graphene honeycomb lattice. with impurity X hybridized to sublattice site A. Only hopping t between sublattices A and B as well as V between X and A exist. Created using VESTA [13].

velopment of local moments and Mottness occurs at, where in the high V limit, the B atom are responsible. Between these Mott states emerges a metallic state, similar to the topological phase transition of non-interacting bands in the Su-Schrieffer-Heger model [14].

In twisted or untwisted multilayer Graphene systems, the energy scale for the emergence of ordered phases is $O(\text{meV})$, corresponding to temperatures of a few K [15, 16]. In contrast, the energy scale in this decorated Graphene model is set by the hopping t, i.e. $O(\text{eV})$ for Graphene, so that the correlated flat band physics might persist to higher temperatures.

1.1 Lattice Structure

Monolayer graphene forms a honeycomb lattice [17], which is a hexagonal Bravais lattice with a two-atom basis, as can be seen in fig. 1.2a. The primitive lattice vectors of the hexagonal lattice are:

$$\mathbf{a}_1 = \frac{a}{2}\begin{pmatrix} 1 \\ \sqrt{3} \end{pmatrix}, \ \mathbf{a}_2 = \frac{a}{2}\begin{pmatrix} 1 \\ -\sqrt{3} \end{pmatrix} \tag{1.1}$$

with lattice constant $a = \sqrt{3}a_0 \approx 2.46\,\text{Å}$, using the nearest-neighbor distance a_0. The vectors from atom A to the nearest-neighbor atoms B_i $(i = 1, 2, 3,)$ are

$$\delta_{AB,1} = \begin{pmatrix} 0 \\ \frac{a}{\sqrt{3}} \end{pmatrix}, \ \delta_{AB,2} = \begin{pmatrix} \frac{a}{2} \\ -\frac{a}{2\sqrt{3}} \end{pmatrix}, \ \delta_{AB,3} = \begin{pmatrix} -\frac{a}{2} \\ -\frac{a}{2\sqrt{3}} \end{pmatrix} \tag{1.2}$$

(a) (b)

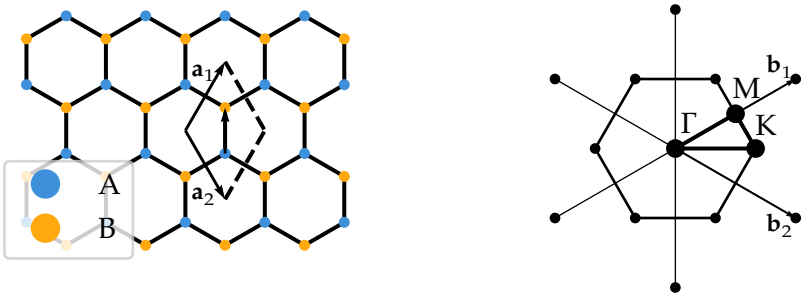

Figure 1.2 – (a) Graphene lattice structure with primitive lattice vectors $\mathbf{a}_1$, $\mathbf{a}_2$ and (b) Brillouin zone with reciprocal vectors $\mathbf{b}_1$, $\mathbf{b}_2$. Both images created with lattpy [18]

and the vectors from atom B to the nearest-neighbor atoms A_i $(i = 1, 2, 3,)$ are

$$\delta_{BA,1} = \begin{pmatrix} 0 \\ -\frac{a}{\sqrt{3}} \end{pmatrix}, \; \delta_{BA,2} = \begin{pmatrix} -\frac{a}{2} \\ \frac{a}{2\sqrt{3}} \end{pmatrix}, \; \delta_{BA,3} = \begin{pmatrix} \frac{a}{2} \\ \frac{a}{2\sqrt{3}} \end{pmatrix} . \tag{1.3}$$

The primitive reciprocal lattice vectors $\mathbf{b}_1$, $\mathbf{b}_2$ fulfill:

$$\mathbf{a}_1 \cdot \mathbf{b}_1 = \mathbf{a}_2 \cdot \mathbf{b}_2 = 2\pi \tag{1.4}$$

$$\mathbf{a}_1 \cdot \mathbf{b}_2 = \mathbf{a}_2 \cdot \mathbf{b}_1 = 0 \,, \tag{1.5}$$

so that

$$\mathbf{b}_1 = \frac{2\pi}{a} \begin{pmatrix} 1 \\ \frac{1}{\sqrt{3}} \end{pmatrix}, \; \mathbf{b}_2 = \frac{2\pi}{a} \begin{pmatrix} 1 \\ -\frac{1}{\sqrt{3}} \end{pmatrix} . \tag{1.6}$$

The first Brillouin zone of the hexagonal lattice is shown in fig. 1.2b, with the points of high symmetry

$$\Gamma = \begin{pmatrix} 0 \\ 0 \end{pmatrix}, \; \mathrm{M} = \frac{\pi}{a} \begin{pmatrix} 1 \\ \frac{1}{\sqrt{3}} \end{pmatrix}, \; \mathrm{K} = \frac{4\pi}{3a} \begin{pmatrix} 1 \\ 0 \end{pmatrix} . \tag{1.7}$$

The elemental model as shown in fig. 1.1 has the following kinetic terms:

$$H_0 = -t \sum_{\langle ij\rangle,\sigma} c_{i,\sigma}^{(\mathrm{A}),\dagger} c_{j,\sigma}^{(\mathrm{B})} + V \sum_{i,\sigma\sigma'} d_{i,\sigma}^{\dagger} c_{i,\sigma'}^{(\mathrm{A})} + \text{h.c.} \tag{1.8}$$

with

- d - operators on the X atom
- $c^{(\epsilon)}$ - operators on the graphene sites ($\epsilon = \mathrm{A}, \mathrm{B}$)
- t - nearest neighbor hopping between Graphene sites
- V - hopping between X and Graphene A sites.

Using the Fourier transformation

$$c_{i\alpha\sigma} = \frac{1}{\sqrt{N}} \sum_{\mathbf{k}} e^{\mathrm{i}\mathbf{k}\mathbf{r}_{i\alpha}} c_{\mathbf{k}\alpha\sigma} \,, \tag{1.9}$$

the hopping term becomes

$$-t \sum_{\langle ij\rangle,\sigma} c_{i,\sigma}^{(\mathrm{A}),\dagger} c_{j,\sigma}^{(\mathrm{B})} \tag{1.10}$$

$$= -t \sum_{i,\delta_{\mathrm{AB}},\sigma} c_{i,\sigma}^{(\mathrm{A})\dagger} c_{i+\delta_{\mathrm{AB}},\sigma}^{(\mathrm{B})} \tag{1.11}$$

$$= -\frac{t}{N^2} \sum_{i,\sigma} \sum_{\mathbf{k},\mathbf{k}',\delta_{\mathrm{AB}}} \left(e^{-\mathrm{i}\mathbf{k}\mathbf{r}_{i\alpha}} c_{\mathbf{k},\sigma}^{(\mathrm{A})\dagger}\right) \left(e^{\mathrm{i}\mathbf{k}'\mathbf{r}_{i\alpha}+\delta_{AB}} c_{\mathbf{k}',\sigma}^{(B)}\right) \tag{1.12}$$

$$= -\frac{t}{N^2} \sum_{\mathbf{k},\mathbf{k}',\delta_{\mathrm{AB}},\sigma} c_{\mathbf{k},\sigma}^{(\mathrm{A})\dagger} c_{\mathbf{k}',\sigma}^{(\mathrm{B})} e^{\mathrm{i}\mathbf{k}'\delta_{\mathrm{AB}}} e^{\mathrm{i}(\mathbf{k}(\delta_A-\delta_B)+\mathbf{k}'(\delta_A-\delta_B))} \sum_i e^{-\mathrm{i}\mathbf{k}\mathbf{R}_i} e^{\mathrm{i}\mathbf{k}'\mathbf{R}_i} \tag{1.13}$$

$$= -\frac{t}{N^2} \sum_{\mathbf{k},\mathbf{k}',\sigma} c_{\mathbf{k},\sigma}^{(\mathrm{A})\dagger} c_{\mathbf{k}',\sigma}^{(\mathrm{B})} \sum_{\delta_{\mathrm{AB}}} e^{\mathrm{i}\mathbf{k}'\delta_{\mathrm{AB}}} e^{\mathrm{i}(\mathbf{k}(\delta_A-\delta_B)+\mathbf{k}'(\delta_A-\delta_B))} \left(N^2 \delta_{\mathbf{k},\mathbf{k}'}\right) \tag{1.14}$$

$$= -t \sum_{\mathbf{k},\sigma} c_{\mathbf{k},\sigma}^{(\mathrm{A})\dagger} c_{\mathbf{k},\sigma}^{(\mathrm{B})} \sum_{\delta_{\mathrm{AB}}} e^{\mathrm{i}(\mathbf{k}\delta_{AB}+2k_y a)} = \sum_{\mathbf{k},\sigma} f_{\mathbf{k}} c_{\mathbf{k},\sigma}^{(\mathrm{A})\dagger} c_{\mathbf{k},\sigma}^{(\mathrm{B})} \,. \tag{1.15}$$

The factor $f_{\mathbf{k}}$ can be written out explicitly using the nearest-neighbor vectors, for example

$$\mathbf{k} \cdot \delta_{\mathbf{AB},\mathbf{1}} = \begin{pmatrix} k_x \\ k_y \end{pmatrix} \cdot \begin{pmatrix} 0 \\ \frac{a}{\sqrt{3}} \end{pmatrix} = \frac{1}{\sqrt{3}} k_y \,. \tag{1.16}$$

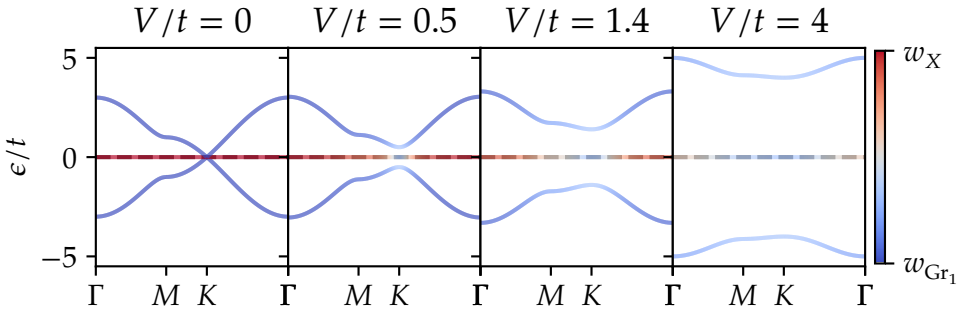

Figure 1.3 – Bands of the non-interacting decorated Graphene model

This gives:

$$f_{\mathbf{k}} = -t \sum_{\delta_{AB}} e^{\mathrm{i}(\mathbf{k}\delta_{AB} + 2k_y a)} \tag{1.17}$$

$$= -t_{\mathrm{Gr}} e^{2\mathrm{i}k_y a} \left(e^{\mathrm{i}\frac{a}{\sqrt{3}}k_y} + e^{\mathrm{i}\frac{a}{2\sqrt{3}}(\sqrt{3}k_x - k_y)} + e^{\mathrm{i}\frac{a}{2\sqrt{3}}(-\sqrt{3}k_x - k_y)} \right) \tag{1.18}$$

$$= -t_{\mathrm{Gr}} e^{2\mathrm{i}k_y a} \left(e^{\mathrm{i}\frac{a}{\sqrt{3}}k_y} + 2e^{-\mathrm{i}\frac{a}{2\sqrt{3}}k_y} \cos\left(\frac{a}{2}k_x\right) \right) . \tag{1.19}$$

Using the fact that $\delta_{\mathrm{BA},i} = -\delta_{\mathrm{AB},i}$, it follows

$$-t \sum_{\delta_{BA}} e^{\mathrm{i}\mathbf{k}\delta_{BA}} = -t \sum_{\delta_{AB}} e^{-\mathrm{i}\mathbf{k}\delta_{AB}} = \left(-t \sum_{\delta_{AB}} e^{\mathrm{i}\mathbf{k}\delta_{AB}} \right)^* = f_{\mathbf{k}}^* , \tag{1.20}$$

which then gives

$$H_0 = \sum_{\mathbf{k},\sigma} C_{\mathbf{k},\sigma}^\dagger \begin{pmatrix} 0 & f_{\mathbf{k}} & V \\ f_{\mathbf{k}}^* & 0 & 0 \\ V & 0 & 0 \end{pmatrix} C_{\mathbf{k},\sigma} \tag{1.21}$$

$$C_{\mathbf{k},\sigma} = \begin{pmatrix} c_{\mathbf{k},\sigma}^{A,\dagger} & c_{\mathbf{k},\sigma}^{B,\dagger} & d_{\mathbf{k},\sigma}^\dagger \end{pmatrix}^T \tag{1.22}$$

The band structure for the non-interacting decorated graphene model is obtained by diagonalizing the matrix in eq. (1.21).
