I.1 BCS theory with momentum dependent coupling

Starting point is a BCS-Hamiltonian with momentum-dependent coupling term $V_{\mathbf{k},\mathbf{k}'}$:

$$H = \sum_{\mathbf{k},\sigma} \epsilon_{\mathbf{k}} c_{\mathbf{k}\sigma}^\dagger c_{\mathbf{k}\sigma} + \sum_{\mathbf{k},\mathbf{k}'} V_{\mathbf{k},\mathbf{k}'} c_{\mathbf{k}\uparrow}^\dagger c_{-\mathbf{k}\downarrow}^\dagger c_{-\mathbf{k}'\downarrow} c_{\mathbf{k}'\uparrow} \quad (\text{I.1})$$

Then similar process as for BCS theory without the momentum-dependent term (Hubbard-Stratonovich decoupling, minimization of mean-field free energy). Gives self-consistent equation for the gap function:

Point out specific difference to BCS theory!

$$\Delta_{\mathbf{k}} = - \sum_{\mathbf{k}'} V_{\mathbf{k},\mathbf{k}'} \frac{\Delta_{\mathbf{k}'}}{2E_{\mathbf{k}'}} \tanh \left(\frac{\beta E_{\mathbf{k}}}{2} \right) \quad (\text{I.2})$$

or at $T = 0$:

$$\Delta_{\mathbf{k}} = - \sum_{\mathbf{k}'} V_{\mathbf{k},\mathbf{k}'} \frac{\Delta_{\mathbf{k}'}}{2E_{\mathbf{k}'}} \quad (\text{I.3})$$

Important note: there is a minus sign in the front! If $V_{\mathbf{k},\mathbf{k}'} < 0$ (a uniformly attractive interaction), the equation is fulfilled by a uniformly positive gap function. In general $V_{\mathbf{k},\mathbf{k}'}$ contains repulsive (positive) terms (in particular stemming from the Coulomb interaction), so the gap function cannot be uniformly positive, it acquires nodes in momentum space. Most satisfying solutions fulfill:

What is the E_k ?

$$\text{sign}(\Delta_{\mathbf{k}}) = - \text{sign}(V_{\mathbf{k},\mathbf{k}'}) \text{sign}(\Delta_{\mathbf{k}'}) \quad (\text{I.4})$$

So for an attractive interaction we have:

$$\text{sign}(\Delta_{\mathbf{k}}) = -(-1) \text{sign}(\Delta_{\mathbf{k}'}) \quad (\text{I.5})$$

So areas in phase space linked by an attractive interaction have the same sign (and areas linked by repulsive interaction have opposite signs)! Solutions like this have the largest gaps and thus the largest mean-field transition temperature .

Why large gap?

Connection from gap to transition temperature?

Are there more?

Two cases :

- Electron-phonon superconductors: interaction is repulsive at high energies, $\Delta_{\mathbf{k}}$ is largely isotropic in momentum space, but changes sign at \approx Debye frequency
- Anisotropic superconductors: $\Delta_{\mathbf{k}}$ is strongly momentum-dependent, acquires nodes in momentum space

The last mechanism is at work in heavy-fermion, high-temperature cuprate and iron-based superconductors.

I.2 Anisotropic pairing

I.2.1 Hubbard interaction

The goal in this section is to derive a BCS-like Hamiltonian with a term

$$V_{\mathbf{k},\mathbf{k}'} \Psi_{\mathbf{k}}^{\dagger} \Psi_{\mathbf{k}'} \quad (\text{I.6})$$

We start from a Hubbard-like interaction term

$$V = \sum_{\mathbf{q}} V_{\mathbf{q}} : \rho_{-\mathbf{q}} \rho_{\mathbf{q}} := \frac{1}{2} \sum_{\mathbf{k}_1, \mathbf{k}_2, \mathbf{q}, \sigma, \sigma'} V_{\mathbf{q}} c_{\mathbf{k}_1 + \mathbf{q}, \sigma}^{\dagger} c_{\mathbf{k}_2 - \mathbf{q}, \sigma'}^{\dagger} c_{\mathbf{k}_2, \sigma'} c_{\mathbf{k}_1, \sigma} \quad (\text{I.7})$$

Proper implementation of normal-ordering

Hubbard-like would be $V_{\mathbf{q}} = U$?

Cooper pairs have zero total momentum and the pairing potential is determined by the interaction on them, so we have

$$\mathbf{k}_1 + \mathbf{k}_2 = 0 \implies \mathbf{k}_1 = -\mathbf{k}_2 =: \mathbf{k}' \quad (\text{I.8})$$

$$\mathbf{k}_1 + \mathbf{q} = -(\mathbf{k}_2 - \mathbf{q}) =: \mathbf{k} \implies \mathbf{k}' + \mathbf{q} = \mathbf{k} \implies \mathbf{q} = \mathbf{k} - \mathbf{k}' \quad (\text{I.9})$$

Show why the third line works!

and we can split up the interaction term

$$V_{\text{BCS}} = \frac{1}{2} \sum_{\mathbf{k}, \mathbf{k}', \sigma, \sigma'} V_{\mathbf{k}-\mathbf{k}'} c_{\mathbf{k}\sigma}^\dagger c_{-\mathbf{k}\sigma'}^\dagger c_{-\mathbf{k}'\sigma'} c_{\mathbf{k}'\sigma} \quad (\text{I.10})$$

$$= \frac{1}{2} \sum_{\mathbf{k}, \mathbf{k}'} V_{\mathbf{k}-\mathbf{k}'} c_{\mathbf{k}\uparrow}^\dagger c_{-\mathbf{k}\downarrow}^\dagger c_{-\mathbf{k}'\downarrow} c_{\mathbf{k}'\uparrow} \quad \left(= \frac{1}{2} V_{\text{BCS}}^{\uparrow\downarrow} \right) \quad (\text{I.11})$$

$$+ \frac{1}{2} \sum_{\mathbf{k}, \mathbf{k}'} V_{\mathbf{k}-\mathbf{k}'} c_{\mathbf{k}\downarrow}^\dagger c_{-\mathbf{k}\uparrow}^\dagger c_{-\mathbf{k}'\uparrow} c_{\mathbf{k}'\downarrow} \quad \left(= \frac{1}{2} V_{\text{BCS}}^{\downarrow\uparrow} = \frac{1}{2} V_{\text{BCS}}^{\uparrow\downarrow} \right) \quad (\text{I.12})$$

$$+ \frac{1}{2} \sum_{\mathbf{k}, \mathbf{k}'} V_{\mathbf{k}-\mathbf{k}'} c_{\mathbf{k}\uparrow}^\dagger c_{-\mathbf{k}\uparrow}^\dagger c_{-\mathbf{k}'\uparrow} c_{\mathbf{k}'\uparrow} \quad \left(= V_{\text{BCS}}^{\uparrow\uparrow} \right) \quad (\text{I.13})$$

$$+ \frac{1}{2} \sum_{\mathbf{k}, \mathbf{k}'} V_{\mathbf{k}-\mathbf{k}'} c_{\mathbf{k}\downarrow}^\dagger c_{-\mathbf{k}\downarrow}^\dagger c_{-\mathbf{k}'\downarrow} c_{\mathbf{k}'\downarrow} \quad \left(= V_{\text{BCS}}^{\downarrow\downarrow} \right) \quad (\text{I.14})$$

$$= V_{\text{BCS}}^{\uparrow\downarrow} + V_{\text{BCS}}^{\uparrow\uparrow} + V_{\text{BCS}}^{\downarrow\downarrow} \quad (\text{I.15})$$

First we treat $V_{\text{BCS}}^{\uparrow\downarrow}$. Pair of opposite spins are neither single nor triplet, because they are not appropriately symmetrised. If we have the pair wave-function

$$F(\mathbf{k})_{\alpha\beta} = \langle \mathbf{k}\alpha, -\mathbf{k}\beta | \mathbf{k}\rho \rangle \quad (\text{I.16})$$

We define spatial parity of this wavefunction:

$$F(-\mathbf{k})_{\alpha\beta} = P F(\mathbf{k})_{\alpha\beta} \quad (\text{I.17})$$

as well as the spin parity:

$$F(\mathbf{k})_{\beta\alpha} = X F(\mathbf{k})_{\alpha\beta}, \quad (\text{I.18})$$

where we define singlets ($X = +1$) and triplets ($X = -1$). The join application of XP is an exchange of fermions, so it should have an eigenvalue -1 . So we have

- even-parity pairs, $P = +1 \implies X = -1$, spin singlets, $(X, P) = (+, -)$
- odd-parity pairs, $P = -1 \implies X = +1$, spin triplets, $(X, P) = (-, +)$

We split up the interaction into the symmetric and asymmetric parts :

$$V_{\text{BCS}} = \sum_{\mathbf{k}, \mathbf{k}'} \left(\frac{V_{\mathbf{k}-\mathbf{k}'} + V_{\mathbf{k}+\mathbf{k}'}}{2} + \frac{V_{\mathbf{k}-\mathbf{k}'} - V_{\mathbf{k}+\mathbf{k}'}}{2} \right) \Psi_{\mathbf{k}}^\dagger \Psi_{\mathbf{k}'} \quad (\text{I.19})$$

$$:= (V_{\mathbf{k}, \mathbf{k}'}^S + V_{\mathbf{k}, \mathbf{k}'}^T) \Psi_{\mathbf{k}}^\dagger \Psi_{\mathbf{k}'} \quad (\text{I.20})$$

Why do we define spatial parity? Only symmetrised wavefunctions physical?

How exactly?

studied superconductors are mostly singlet, pure triplet not found? That's why we split it up! Paper for that?

where we have defined the BCS pairing interaction in the singlet and triplet channel:

$$V_{\mathbf{k},\mathbf{k}'}^{S,T} = \frac{1}{2} (V_{\mathbf{k}-\mathbf{k}'} \pm V_{\mathbf{k}+\mathbf{k}'}) \quad (\text{I.21})$$

explain last step here

The singlet channel is even in \mathbf{k}, \mathbf{k}' :

$$V_{-\mathbf{k},-\mathbf{k}'}^S = \frac{1}{2} (V_{-\mathbf{k}+\mathbf{k}'} \pm V_{-\mathbf{k}-\mathbf{k}'}) = \frac{1}{2} (V_{-(\mathbf{k}-\mathbf{k}')} \pm V_{-(\mathbf{k}+\mathbf{k}')}) = \frac{1}{2} (V_{\mathbf{k}-\mathbf{k}'} \pm V_{\mathbf{k}+\mathbf{k}'}) , \quad (\text{I.22})$$

while the triplet channel is odd in \mathbf{k}, \mathbf{k}' . In the sum:

With everything we write the unequal spin pairing as:

$$V_{\text{BCS}}^{\uparrow\downarrow} = \frac{1}{4} \sum_{\mathbf{k}\mathbf{k}'} \left[V_{\mathbf{k},\mathbf{k}'}^S \Psi_{\mathbf{k}}^{S\dagger} \Psi_{\mathbf{k}'}^S + V_{\mathbf{k},\mathbf{k}'}^T \Psi_{\mathbf{k}}^{T\dagger} \Psi_{\mathbf{k}'}^T \right] \quad (\text{I.23})$$

$$= \sum_{\mathbf{k}\mathbf{k}' \in \frac{1}{2}\text{BZ}} \left[V_{\mathbf{k},\mathbf{k}'}^S \Psi_{\mathbf{k}}^{S\dagger} \Psi_{\mathbf{k}'}^S + V_{\mathbf{k},\mathbf{k}'}^T \Psi_{\mathbf{k}}^{T\dagger} \Psi_{\mathbf{k}'}^T \right] \quad (\text{I.24})$$

vector arrows over the psi (or bold)

The equal spin pairing also includes triplet pairing (these are wrapped up in the vectors) and all in all the BCS pairing potential is:

$$H_{\text{BCS}} = \sum_{\mathbf{k}\mathbf{k}' \in \frac{1}{2}\text{BZ}} \left[V_{\mathbf{k},\mathbf{k}'}^S \Psi_{\mathbf{k}}^{S\dagger} \Psi_{\mathbf{k}'}^S + V_{\mathbf{k},\mathbf{k}'}^T \Psi_{\mathbf{k}}^{T\dagger} \cdot \Psi_{\mathbf{k}'}^T \right] \quad (\text{I.25})$$

How can we access that information in experiment?

In real materials we mostly see singlet pairing , in this case we can just write:

$$H = \sum_{\mathbf{k}\mathbf{k}' \in \frac{1}{2}\text{BZ}} V_{\mathbf{k},\mathbf{k}'}^S (c_{\mathbf{k}\uparrow}^\dagger c_{-\mathbf{k}\downarrow}^\dagger) (c_{-\mathbf{k}'\downarrow} c_{\mathbf{k}'\uparrow}) \quad (\text{I.26})$$

Source for that?

I.2.2 Magnetic interaction

Starting point here is a magnetic interaction:

$$V_{\text{mag}} = \frac{1}{2} \sum_{\mathbf{q}} J_{\mathbf{q}} [\mathbf{S}_{-\mathbf{q}} \cdot \mathbf{S}_{\mathbf{q}}] \quad (\text{I.27})$$

$$= \frac{1}{2} \sum_{\mathbf{k}_1, \mathbf{k}_2, \mathbf{q}} J_{\mathbf{q}} c_{\mathbf{k}_1+\mathbf{q}\alpha}^\dagger c_{\mathbf{k}_2-\mathbf{q}\gamma}^\dagger \left(\frac{\sigma}{2} \right)_{\alpha\beta} \left(\frac{\sigma}{2} \right)_{\gamma\delta} c_{\mathbf{k}_2\delta} c_{\mathbf{k}_1\beta} \quad (\text{I.28})$$

Important point: eigenvalues of $\mathbf{S}_1 \cdot \mathbf{S}_2$ are different for singlet and triplet states:

$$\mathbf{S}_1 \cdot \mathbf{S}_2 = \begin{cases} +\frac{1}{4} & (\text{triplet}) \\ -\frac{3}{4} & (\text{singlet}) \end{cases} \quad (\text{I.29})$$

These eigenvalues enter as prefactors into the pairing potentials:

$$V_{\mathbf{k},\mathbf{k}'}^S = -\frac{3}{4} \left(\frac{J_{\mathbf{k}-\mathbf{k}'} + J_{\mathbf{k}+\mathbf{k}'}}{2} \right) \quad (\text{I.30})$$

$$V_{\mathbf{k},\mathbf{k}'}^T = \frac{1}{4} \left(\frac{J_{\mathbf{k}-\mathbf{k}'} - J_{\mathbf{k}+\mathbf{k}'}}{2} \right) \quad (\text{I.31})$$

So antiferromagnetic interactions ($J_{\mathbf{k}-\mathbf{k}'} > 0 \implies V_{\mathbf{k},\mathbf{k}'}^S < 0$) attract in the singlet channel, while ferromagnetic interactions ($J_{\mathbf{k}-\mathbf{k}'} < 0 \implies V_{\mathbf{k},\mathbf{k}'}^T < 0$) attracts in the triplet channel.

I.3 d-wave superconductivity in two dimensions - cuprates

Cuprate superconductors cannot be understood in Fermi liquid theory.

Three regimes :

- Undoped: antiferromagnetic Mott insulators
- Doped: d-wave superconductors
- Over-doped: Fermi liquid behaviours reoccurs, BCS treatment is applicable

Approximate by 2D tight-binding lattice (with nearest-neighbour hopping strength t) with

$$\epsilon_{\mathbf{k}} = -2t(\cos(k_x a) + \cos(k_y a)) - \mu \quad (\text{I.32})$$

interacting via onsite Coulomb repulsion and nearest-neighbour antiferromagnetic interaction:

$$H = \sum_{\mathbf{k}\sigma} \epsilon_{\mathbf{k}} c_{\mathbf{k}\sigma}^\dagger c_{\mathbf{k}\sigma} + \sum_j U n_{j\uparrow} n_{j\downarrow} + J \sum_{\langle i,j \rangle} \mathbf{S}_i \cdot \mathbf{S}_j \quad (\text{I.33})$$

A bit more information on history, structure etc.

How doped?

Why can we only treat BCS when we also have Fermi liquid?

Do we just treat this case in the following?

In momentum space:

$$H = \sum_{\mathbf{k}\sigma} \epsilon_{\mathbf{k}} c_{\mathbf{k}\sigma}^\dagger c_{\mathbf{k}\sigma} + \frac{1}{2} \sum_{\mathbf{q}} U \rho_{-\mathbf{q}} \rho_{\mathbf{q}} + J \sum_{\mathbf{q}} \mathbf{S}_{-\mathbf{q}} \cdot \mathbf{S}_{\mathbf{q}} \quad (\text{I.34})$$

with $J_{\mathbf{q}} = 2J (\cos(q_x a) + \cos(q_y a))$. From the treatment of the Hubbard and magnetic interaction earlier we can get the singlet interaction

$$V_{\mathbf{k},\mathbf{k}'} = U - \frac{3J}{2} (c_x c_{x'} + c_y c_{y'}) \quad (\text{I.35})$$

where we use the abbreviation $c_x = \cos(k_x a)$. So the mean-field BCS Hamiltonian is

$$H = \sum_{\mathbf{k}\sigma} \epsilon_{\mathbf{k}} c_{\mathbf{k}\sigma}^\dagger c_{\mathbf{k}\sigma} + \sum_{\mathbf{k}\mathbf{k}'} \left(U - \frac{3J}{2} (c_x c_{x'} + c_y c_{y'}) \right) \quad (\text{I.36})$$

Looking at the gap equation

$$\Delta_{\mathbf{k}} = - \sum_{\mathbf{k}'} V_{\mathbf{k},\mathbf{k}'} \frac{\Delta_{\mathbf{k}'}}{2E_{\mathbf{k}'}} \tanh \left(\frac{\beta E_{\mathbf{k}'}}{2} \right), \quad (\text{I.37})$$

we see that it preserves the symmetries of the pair ($\hat{=}$ symmetries of $\Delta_{\mathbf{k}}$). We divide the interaction into two parts:

$$V_{\mathbf{k}\mathbf{k}'}^S = U - \frac{3J}{4} (c_x + c_y)(c_{x'} + c_{y'}) \quad (\text{I.38})$$

$$V_{\mathbf{k}\mathbf{k}'}^D = -\frac{3J}{2} (c_x - c_y)(c_{x'} - c_{y'}) \quad (\text{I.39})$$

$$V_{\mathbf{k}\mathbf{k}'}^S + V_{\mathbf{k}\mathbf{k}'}^D = U - \frac{3J}{4} (c_x c_{x'} + c_x c_{y'} + c_{x'} c_y + c_y c_{y'}) \quad (\text{I.40})$$

$$- \frac{3J}{4} (c_x c_{x'} - c_x c_{y'} - c_{x'} c_y + c_y c_{y'}) \quad (\text{I.41})$$

$$= U - \frac{3J}{2} (c_x c_{x'} + c_y c_{y'}) = V_{\mathbf{k},\mathbf{k}'} \quad (\text{I.42})$$

We call $\frac{3J}{4} (c_x + c_y)(c_{x'} + c_{y'})$ the extended s-wave term. The s-wave term is invariant under 90° rotations of \mathbf{k} or \mathbf{k}' , whereas the d-wave term changes

$$V_{\mathbf{k}\mathbf{k}'}^S = V_{\mathbf{k}R\mathbf{k}'}^S \quad (\text{I.43})$$

$$V_{\mathbf{k}\mathbf{k}'}^D = -V_{\mathbf{k}R\mathbf{k}'}^D \quad (\text{I.44})$$

with $R\mathbf{k} = (-k_y, k_x)$. Another point to note is that in the d-wave term, there is no onsite Coulomb interaction. So a condensate with d-wave symmetry,

$$\Delta_{\mathbf{k}}^D = \Delta_D(c_x - c_y) \quad (\text{I.45})$$

$$\Delta_{R\mathbf{k}}^D = -\Delta_{\mathbf{k}}^D \quad (\text{I.46})$$

couples to cooper pairs via d-wave interaction , because

$$\sum_{\mathbf{k}'} V_{\mathbf{k}\mathbf{k}'}^S \Delta_{\mathbf{k}'}^D(\dots) = 0 \quad (\text{I.47})$$

(see gap equation, it preserves the symmetry of the pair). A condensate with extended s-wave symmetry

$$\Delta_{\mathbf{k}}^S = \Delta_1 + \Delta_2(c_x + c_y) \quad (\text{I.48})$$

vanishes when integrated with the d-wave part of the interaction. This means the two types of pairing are symmetry decoupled and moreover, the symmetry of the d-wave pair decouples against the local Coulomb pseudopotential. The quasiparticle energy for the d-wave condensate is :

$$E_{\mathbf{k}} = \sqrt{\epsilon_{\mathbf{k}}^2 + \Delta_{\mathbf{k}}^2(c_y - c_x)^2} \quad (\text{I.49})$$

It vanishes at intersections of nodes (where $\Delta_{\mathbf{k}} = 0$) and the Fermi surface (where $\epsilon_{\mathbf{k}} = 0$). At these points the dispersion can be linearized, they form Dirac cones of excitations with a relativistic dispersion . We can approximately solve the gap equation and get

$$\Delta_D(c_y - c_x) = \Delta_D(k_x^2 - k_y^2) = \Delta_0 \cos(2\theta) \quad (\text{I.50})$$

The dependence $\Delta \propto \cos(2\theta)$ is typical for an $l = 2$ Cooper pair. The quasiparticle energy is then

$$E_{\mathbf{k}} = \sqrt{\epsilon_{\mathbf{k}}^2 + (\Delta_0 \cos(2\theta))^2} \quad (\text{I.51})$$

The d-wave density of states does not have a clear gap, but instead a V-shaped structure. This linear DOS across the gap is due to the Dirac cones.

What is the relationship between gap and interaction? aka where does this equation come from?

What quasiparticle?

Insert image here!

What is the exact dispersion?

How exactly typical? $l = 2$?

Visualise that somehow?

Insert image here!
