I Green's Function Formalism

Source: [1]

Most general non-interacting electronic Hamiltonian in second quantization:

$$H_0 = \sum_{i,j,\sigma}$$ (I.1)

with lattice coordinates i, j and spin σ.

One particle Green's function (many-body object, coming from the Hubbard model):

$$G(\mathbf{k}, i\omega_n) = \frac{1}{i\omega_n + \mu - \epsilon_{\mathbf{k}} - \Sigma(\mathbf{k}, i\omega_n)}$$ (I.2)

with the self energy $\Sigma(i\omega_n)$ coming from the solution of the effect on-site problem:

The Dyson equation

$$G(\mathbf{k}, i\omega_n) = (G_0(\mathbf{k}, i\omega_n) - \Sigma(\mathbf{k}, i\omega_n))^{-1}$$ (I.3)

relates the non-interacting Greens function $G_0(\mathbf{k}, i\omega_n)$ and the fully-interacting Greens function $G(\mathbf{k}, i\omega_n)$ (inversion of a matrix!).

Greens functions introduction (Bruus Flensberg or Coleman or something)

Show how Green's functions can be used to describe many-body effects -> Spectral function, self-energy

Add citations for: exact limit in infinite dimension, Anderson impurity model

Add Mott transition as an achievement

II Dynamical Mean-Field Theory

Source: Georges et al. - "Dynamical mean-field theory of strongly correlated fermion systems and the limit of infinite dimensions" [2]

With help from [3] and [4] to make it more concise.

Most general non-interacting electronic Hamiltonian in second quantization:

$$H_0 = \sum_{i,j,\sigma} \tag{II.1}$$

with lattice coordinates i, j and spin σ.

One particle Green's function (many-body object, coming from the Hubbard model):

$$G(\mathbf{k}, i\omega_n) = \frac{1}{i\omega_n + \mu - \epsilon_{\mathbf{k}} - \Sigma(\mathbf{k}, i\omega_n)} \tag{II.2}$$

with the self energy $\Sigma(i\omega_n)$ coming from the solution of the effect on-site problem:

The Dyson equation

$$G(\mathbf{k}, i\omega_n) = (G_0(\mathbf{k}, i\omega_n) - \Sigma(\mathbf{k}, i\omega_n))^{-1} \tag{II.3}$$

relates the non-interacting Greens function $G_0(\mathbf{k}, i\omega_n)$ and the fully-interacting Greens function $G(\mathbf{k}, i\omega_n)$ (inversion of a matrix!).

Greens functions introduction (Bruus Flensberg or Coleman or something)

Show how Green's functions can be used to describe many-body effects -> Spectral function, self-energy

III d-wave Superconductivity

Source: Coleman - *Introduction to Many-Body Physics* [5, ch. 15]

III.1 BCS theory with momentum dependent coupling

Starting point is a BCS-Hamiltonian with momentum-dependent coupling term $V_{\mathbf{k},\mathbf{k}'}$:

$$H = \sum_{\mathbf{k},\sigma} \epsilon_{\mathbf{k}} c_{\mathbf{k}\sigma}^{\dagger} c_{\mathbf{k}\sigma} + \sum_{\mathbf{k},\mathbf{k}'} V_{\mathbf{k},\mathbf{k}'} c_{\mathbf{k}\uparrow}^{\dagger} c_{-\mathbf{k}\downarrow}^{\dagger} c_{-\mathbf{k}'\downarrow} c_{\mathbf{k}'\uparrow} \qquad \text{(III.1)}$$

The original idea by Bardeen, Cooper and Schrieffer uses the coupling

$$V_{\mathbf{k},\mathbf{k}'} = \begin{cases} -\frac{g_0}{V} \ , \ |\epsilon_{\mathbf{k}}| < \omega_D \\ 0 \end{cases} \qquad \text{(III.2)}$$

Then similar process as for BCS theory without the momentum-dependent term (Hubbard-Stratonovich decoupling, minimization of mean-field free energy). Gives self-consistent equation for the gap function:

$$\Delta_{\mathbf{k}} = -\sum_{\mathbf{k}'} V_{\mathbf{k},\mathbf{k}'} \frac{\Delta_{\mathbf{k}'}}{2E_{\mathbf{k}'}} \tanh\left(\frac{\beta E_{\mathbf{k}}}{2}\right) \qquad \text{(III.3)}$$

or at $T = 0$:

$$\Delta_{\mathbf{k}} = -\sum_{\mathbf{k}'} V_{\mathbf{k},\mathbf{k}'} \frac{\Delta_{\mathbf{k}'}}{2E_{\mathbf{k}'}} \qquad \text{(III.4)}$$

Important note: there is a minus sign in the front! If $V_{\mathbf{k},\mathbf{k}'} < 0$ (a uniformly attractive interaction), the equation is fulfilled by a uniformly positive gap function. In general $V_{\mathbf{k},\mathbf{k}'}$ contains repulsive (positive) terms (in particular stemming from the Coulomb interaction), so the gap function cannot be

> Point out specific difference to BCS theory!

> What is the E_k?

5

uniformly positive, it acquires nodes in momentum space. Most satisfying solutions fulfill:

$$\text{sign}(\Delta_{\mathbf{k}}) = -\text{sign}(V_{\mathbf{k},\mathbf{k}'})\,\text{sign}(\Delta_{\mathbf{k}'}) \tag{III.5}$$

So for an attractive interaction we have:

$$\text{sign}(\Delta_{\mathbf{k}}) = -(-1)\,\text{sign}(\Delta_{\mathbf{k}'}) \tag{III.6}$$

So areas in phase space linked by an attractive interaction have the same sign (and areas linked by repulsive interaction have opposite signs)! Solutions like this have the largest gaps and thus the largest mean-field transition temperature .

Two cases :

- Electron-phonon superconductors: interaction is repulsive at high energies, $\Delta_{\mathbf{k}}$ is largely isotropic in momentum space, but changes sign at $\approx$ Debye frequency
- Anisotropic superconductors: $\Delta_{\mathbf{k}}$ is strongly momentum-dependent, acquires nodes in momentum space

The last mechanism is at work in heavy-fermion, high-temperature cuprate and iron-based superconductors.

III.2 Anisotropic pairing

III.2.1 Hubbard interaction

The goal in this section is to derive a BCS-like Hamiltonian with a term

$$V_{\mathbf{k},\mathbf{k}'}\Psi_{\mathbf{k}}^{\dagger}\Psi_{\mathbf{k}'} \tag{III.7}$$

We start from a Hubbard-like interaction term

$$V = \sum_{\mathbf{q}} V_{\mathbf{q}} : \rho_{-\mathbf{q}}\rho_{\mathbf{q}} := \frac{1}{2}\sum_{\mathbf{k}_1,\mathbf{k}_2,\mathbf{q},\sigma,\sigma'} V_{\mathbf{q}} c_{\mathbf{k}_1+\mathbf{q}\sigma}^{\dagger} c_{\mathbf{k}_2-\mathbf{q}\sigma'}^{\dagger} c_{\mathbf{k}_2\sigma'} c_{\mathbf{k}_1\sigma} \tag{III.8}$$

Margin notes:

- Why large gap?
- Connection from gap to transition temperature?
- Are there more?
- Proper implementation of normal-ordering
- Hubbard-like would be $V_q = U$?

Cooper pairs have zero total momentum and the pairing potential is determined by the interaction on them, so we have

$$\mathbf{k}_1 + \mathbf{k}_2 = 0 \implies \mathbf{k}_1 = -\mathbf{k}_2 =: \mathbf{k}' \tag{III.9}$$

$$\mathbf{k}_1 + \mathbf{q} = -(\mathbf{k}_2 - \mathbf{q}) =: \mathbf{k} \implies \mathbf{k}' + \mathbf{q} = \mathbf{k} \implies \mathbf{q} = \mathbf{k} - \mathbf{k}' \tag{III.10}$$

and we can split up the interaction term

> Show why the third line works!

$$V_{\mathrm{BCS}} = \frac{1}{2} \sum_{\mathbf{k},\mathbf{k}',\sigma,\sigma'} V_{\mathbf{k}-\mathbf{k}'} c_{\mathbf{k}\sigma}^\dagger c_{-\mathbf{k}\sigma'}^\dagger c_{-\mathbf{k}'\sigma'} c_{\mathbf{k}'\sigma} \tag{III.11}$$

$$= \frac{1}{2} \sum_{\mathbf{k},\mathbf{k}'} V_{\mathbf{k}-\mathbf{k}'} c_{\mathbf{k}\uparrow}^\dagger c_{-\mathbf{k}\downarrow}^\dagger c_{-\mathbf{k}'\downarrow} c_{\mathbf{k}'\uparrow} \qquad \left(= \frac{1}{2} V_{\mathrm{BCS}}^{\uparrow\downarrow} \right) \tag{III.12}$$

$$+ \frac{1}{2} \sum_{\mathbf{k},\mathbf{k}'} V_{\mathbf{k}-\mathbf{k}'} c_{\mathbf{k}\downarrow}^\dagger c_{-\mathbf{k}\uparrow}^\dagger c_{-\mathbf{k}'\uparrow} c_{\mathbf{k}'\downarrow} \qquad \left(= \frac{1}{2} V_{\mathrm{BCS}}^{\downarrow\uparrow} = \frac{1}{2} V_{\mathrm{BCS}}^{\uparrow\downarrow} \right) \tag{III.13}$$

$$+ \frac{1}{2} \sum_{\mathbf{k},\mathbf{k}'} V_{\mathbf{k}-\mathbf{k}'} c_{\mathbf{k}\uparrow}^\dagger c_{-\mathbf{k}\uparrow}^\dagger c_{-\mathbf{k}'\uparrow} c_{\mathbf{k}'\uparrow} \qquad \left(= V_{\mathrm{BCS}}^{\uparrow\uparrow} \right) \tag{III.14}$$

$$+ \frac{1}{2} \sum_{\mathbf{k},\mathbf{k}'} V_{\mathbf{k}-\mathbf{k}'} c_{\mathbf{k}\downarrow}^\dagger c_{-\mathbf{k}\downarrow}^\dagger c_{-\mathbf{k}'\downarrow} c_{\mathbf{k}'\downarrow} \qquad \left(= V_{\mathrm{BCS}}^{\downarrow\downarrow} \right) \tag{III.15}$$

$$= V_{\mathrm{BCS}}^{\uparrow\downarrow} + V_{\mathrm{BCS}}^{\uparrow\uparrow} + V_{\mathrm{BCS}}^{\downarrow\downarrow} \tag{III.16}$$

First we treat $V_{\mathrm{BCS}}^{\uparrow\downarrow}$. Pair of opposite spins are neither single nor triplet, because they are not appropiately symmetrised. If we have the pair wavefunction

> Why do we define spatial parity? Only symmetrised wavefunctions physical?

$$F(\mathbf{k})_{\alpha\beta} = \langle \mathbf{k}\alpha, -\mathbf{k}\beta | \, |\mathbf{k}\rho\rangle \tag{III.17}$$

We define spatial parity of this wavefunction:

$$F(-\mathbf{k})_{\alpha\beta} = P F(\mathbf{k})_{\alpha\beta} \tag{III.18}$$

as well as the spin parity:

$$F(\mathbf{k})_{\beta\alpha} = X F(\mathbf{k})_{\alpha\beta} \, , \tag{III.19}$$

where we define singlets ($X = +1$) and triplets ($X = -1$). The join application of XP is an exchange of fermions, so it should have an eigenvalue -1. So we have

- even-parity pairs, $P = +1 \implies X = -1$, spin singlets, $(X, P) = (+, -)$
- odd-parity pairs, $P = -1 \implies X = +1$, spin triplets, $(X, P) = (-, +)$

We split up the interaction into the symmetric and asymmetric parts :

$$V_{\mathrm{BCS}} = \sum_{\mathbf{k},\mathbf{k}'} \left(\frac{V_{\mathbf{k}-\mathbf{k}'} + V_{\mathbf{k}+\mathbf{k}'}}{2} + \frac{V_{\mathbf{k}-\mathbf{k}'} - V_{\mathbf{k}+\mathbf{k}'}}{2} \right) \Psi_{\mathbf{k}}^{\dagger} \Psi_{\mathbf{k}'} \tag{III.20}$$

$$:= \left(V_{\mathbf{k},\mathbf{k}'}^{S} + V_{\mathbf{k},\mathbf{k}'}^{T} \right) \Psi_{\mathbf{k}}^{\dagger} \Psi_{\mathbf{k}'} , \tag{III.21}$$

where we have defined the BCS pairing interaction in the singlet and triplet channel:

$$V_{\mathbf{k},\mathbf{k}'}^{S,T} = \frac{1}{2} \left(V_{\mathbf{k}-\mathbf{k}'} \pm V_{\mathbf{k}+\mathbf{k}'} \right) \tag{III.22}$$

The singlet channel is even in $\mathbf{k}, \mathbf{k}'$:

$$V_{-\mathbf{k},-\mathbf{k}'}^{S} = \frac{1}{2} \left(V_{-\mathbf{k}+\mathbf{k}'} \pm V_{-\mathbf{k}-\mathbf{k}'} \right) = \frac{1}{2} \left(V_{-(\mathbf{k}-\mathbf{k}')} \pm V_{-(\mathbf{k}+\mathbf{k}')} \right) = \frac{1}{2} \left(V_{\mathbf{k}-\mathbf{k}'} \pm V_{\mathbf{k}+\mathbf{k}'} \right) , \tag{III.23}$$

while the triplet channel is odd in $\mathbf{k}, \mathbf{k}'$. In the sum:

With everything we write the unequal spin pairing as:

$$V_{\mathrm{BCS}}^{\uparrow\downarrow} = \frac{1}{4} \sum_{\mathbf{k}\mathbf{k}'} \left[V_{\mathbf{k},\mathbf{k}'}^{S} \Psi_{\mathbf{k}}^{S\dagger} \Psi_{\mathbf{k}'}^{S} + V_{\mathbf{k},\mathbf{k}'}^{T} \Psi_{\mathbf{k}}^{T\dagger} \Psi_{\mathbf{k}'}^{T} \right] \tag{III.24}$$

$$= \sum_{\mathbf{k}\mathbf{k}' \in \frac{1}{2}\mathrm{BZ}} \left[V_{\mathbf{k},\mathbf{k}'}^{S} \Psi_{\mathbf{k}}^{S\dagger} \Psi_{\mathbf{k}'}^{S} + V_{\mathbf{k},\mathbf{k}'}^{T} \Psi_{\mathbf{k}}^{T\dagger} \Psi_{\mathbf{k}'}^{T} \right] \tag{III.25}$$

The equal spin pairing also includes triplet pairing (these are wrapped up in the vectors) and all in all the BCS pairing potential is:

$$V_{\mathrm{BCS}} = \sum_{\mathbf{k}\mathbf{k}' \in \frac{1}{2}\mathrm{BZ}} \left[V_{\mathbf{k},\mathbf{k}'}^{S} \Psi_{\mathbf{k}}^{S\dagger} \Psi_{\mathbf{k}'}^{S} + V_{\mathbf{k},\mathbf{k}'}^{T} {}_{*} \Psi_{\mathbf{k}}^{T\dagger} \cdot {}_{*} \Psi_{\mathbf{k}'}^{T} \right] \tag{III.26}$$

In real materials we mostly see singlet pairing , in this case we can just write:

$$V_{\mathrm{BCS}} = \sum_{\mathbf{k}\mathbf{k}' \in \frac{1}{2}\mathrm{BZ}} V_{\mathbf{k},\mathbf{k}'}^{S} (c_{\mathbf{k}\uparrow}^{\dagger} c_{-\mathbf{k}\downarrow}^{\dagger})(c_{-\mathbf{k}'\downarrow} c_{\mathbf{k}'\uparrow}) \tag{III.27}$$

Margin notes:

How exactly?

studied superconductors are mostly singlet, pure triplet not found? Thats why we split it up! Paper for that?

explain last step here

vector arrows over the psi (or bold)

How can we access that information in experiment?

Source for that?

III.2.2 Magnetic interaction

Starting point here is a magnetic interaction:

$$V_{\text{mag}} = \frac{1}{2} \sum_{\mathbf{q}} J_{\mathbf{q}} \left[\mathbf{S}_{-\mathbf{q}} \cdot \mathbf{S}_{\mathbf{q}} \right] \tag{III.28}$$

$$= \frac{1}{2} \sum_{\mathbf{k}_1, \mathbf{k}_2, \mathbf{q}} J_{\mathbf{q}} c^{\dagger}_{\mathbf{k}_1 + \mathbf{q} \alpha} c^{\dagger}_{\mathbf{k}_2 - \mathbf{q} \gamma} \left(\frac{\sigma}{2} \right)_{\alpha\beta} \left(\frac{\sigma}{2} \right)_{\gamma\delta} c_{\mathbf{k}_2 \delta} c_{\mathbf{k}_1 \beta} \tag{III.29}$$

Important point: eigenvalues of $\mathbf{S}_1 \cdot \mathbf{S}_2$ are different for singlet and triplet states:

$$\mathbf{S}_1 \cdot \mathbf{S}_2 = \begin{cases} +\frac{1}{4} & \text{(triplet)} \\ -\frac{3}{4} & \text{(singlet)} \end{cases} \tag{III.30}$$

These eigenvalues enter as prefactors into the pairing potentials:

$$V^S_{\mathbf{k},\mathbf{k}'} = -\frac{3}{4} \left(\frac{J_{\mathbf{k}-\mathbf{k}'} + J_{\mathbf{k}+\mathbf{k}'}}{2} \right) \tag{III.31}$$

$$V^T_{\mathbf{k},\mathbf{k}'} = \frac{1}{4} \left(\frac{J_{\mathbf{k}-\mathbf{k}'} - J_{\mathbf{k}+\mathbf{k}'}}{2} \right) \tag{III.32}$$

So antiferromagnetic interactions ($J_{\mathbf{k}-\mathbf{k}'} > 0 \implies V^S_{\mathbf{k},\mathbf{k}'} < 0$) attract in the singlet channel, while ferromagnetic interactions ($J_{\mathbf{k}-\mathbf{k}'} < 0 \implies V^T_{\mathbf{k},\mathbf{k}'} < 0$) attracts in the triplet channel.

III.3 d-wave superconductivity in two dimensions - cuprates

Cuprate superconductors cannot be understood in Fermi liquid theory.
Three regimes :

- Undoped: antiferromagnetic Mott insulators
- Doped: d-wave superconductors
- Over-doped: Fermi liquid behaviours reoccurs, BCS treatment is applicable

A bit more information on history, structure etc.

How doped?

Why can we only treat BCS when we also have Fermi liquid?

Do we just treat this case in the following?

Approximate by 2D tight-binding lattice (with nearest-neighbour hopping strength t) with

$$\epsilon_{\mathbf{k}} = -2t(\cos{(k_x a)} + \cos{(k_y a)}) - \mu \tag{III.33}$$

interacting via onsite Coulomb repulsion and nearest-neighbour antiferromagnetic interaction:

$$H = \sum_{\mathbf{k}\sigma} \epsilon_{\mathbf{k}} c_{\mathbf{k}\sigma}^{\dagger} c_{\mathbf{k}\sigma} + \sum_j U n_{j\uparrow} n_{j\downarrow} + J \sum_{\langle i,j \rangle} \mathbf{S}_i \cdot \mathbf{S}_j \tag{III.34}$$

In momentum space:

$$H = \sum_{\mathbf{k}\sigma} \epsilon_{\mathbf{k}} c_{\mathbf{k}\sigma}^{\dagger} c_{\mathbf{k}\sigma} + \frac{1}{2} \sum_{\mathbf{q}} U \rho_{-\mathbf{q}} \rho_{\mathbf{q}} + J \sum_{\mathbf{q}} \mathbf{S}_{-\mathbf{q}} \cdot \mathbf{S}_{\mathbf{q}} \tag{III.35}$$

with $J_{\mathbf{q}} = 2J \left(\cos{(q_x a)} + \cos{(q_y a)} \right)$. From the treatment of the Hubbard and magnetic interaction earlier we can get the singlet interaction

$$V_{\mathbf{k},\mathbf{k}'} = U - \frac{3J}{2} \left(c_x c_{x'} + c_y c_{y'} \right) \tag{III.36}$$

where we use the abbreviation $c_x = \cos{(k_x a)}$. So the mean-field BCS Hamiltonian is

$$H = \sum_{\mathbf{k}\sigma} \epsilon_{\mathbf{k}} c_{\mathbf{k}\sigma}^{\dagger} c_{\mathbf{k}\sigma} + \sum_{\mathbf{k}\mathbf{k}'} \left(U - \frac{3J}{2} \left(c_x c_{x'} + c_y c_{y'} \right) \right) \tag{III.37}$$

Looking at the gap equation

$$\Delta_{\mathbf{k}} = -\sum_{\mathbf{k}'} V_{\mathbf{k},\mathbf{k}'} \frac{\Delta_{\mathbf{k}'}}{2 E_{\mathbf{k}'}} \tanh{\left(\frac{\beta E_{\mathbf{k}}}{2} \right)}, \tag{III.38}$$

we see that the interaction preserves the symmetries of the pair ($\hat{=}$ symmetries of $\Delta_{\mathbf{k}}$). We divide the interaction into two parts:

Margin notes:

- $V_q^{singlet}$ as well?
- Put table here as well?
- Calculate that fully
- Why is the symmetry preserved? And why are the symmetries of the pair conserved? Are these the same as of Δ_k?

$$V_{\mathbf{k},\mathbf{k}'}^{S} = U - \frac{3J}{4}(c_x + c_y)(c_{x'} + c_{y'}) \tag{III.39}$$

$$V_{\mathbf{k},\mathbf{k}'}^{D} = -\frac{3J}{2}(c_x - c_y)(c_{x'} - c_{y'}) \tag{III.40}$$

$$V_{\mathbf{k},\mathbf{k}'}^{S} + V_{\mathbf{k},\mathbf{k}'}^{D} = U - \frac{3J}{4}(c_x c_{x'} + c_x c_{y'} + c_{x'} c_y + c_y c_{y'}) \tag{III.41}$$

$$-\frac{3J}{4}(c_x c_{x'} - c_x c_{y'} - c_{x'} c_y + c_y c_{y'}) \tag{III.42}$$

$$= U - \frac{3J}{2}(c_x c_{x'} + c_y c_{y'}) = V_{\mathbf{k},\mathbf{k}'} \tag{III.43}$$

We call $\frac{3J}{4}(c_x + c_y)(c_{x'} + c_{y'})$ the extended s-wave term. The s-wave term is invariant under $90°$ rotations of $\mathbf{k}$ or $\mathbf{k}'$, whereas the d-wave term changes sign :

> **Calculate that**

$$V_{\mathbf{k},\mathbf{k}'}^{S} = V_{\mathbf{k}R\mathbf{k}'}^{S} \tag{III.44}$$

$$V_{\mathbf{k},\mathbf{k}'}^{D} = -V_{\mathbf{k}R\mathbf{k}'}^{D} \tag{III.45}$$

with $R\mathbf{k} = (-k_y, k_x)$. Another point to note is that in the d-wave term, there is no onsite Coulomb interaction. So a condensate with d-wave symmetry ,

> **Can an s-wave condensate also appear? How is it decided what symmetry the condensate has?**

$$\Delta_{\mathbf{k}}^{D} = \Delta_D(c_x - c_y) \tag{III.46}$$

$$\Delta_{R\mathbf{k}}^{D} = -\Delta_{\mathbf{k}}^{D} \tag{III.47}$$

couples to cooper pairs via d-wave interaction , because

> **What is the relationship between gap and interaction? aka where does this equation come from?**

$$\sum_{\mathbf{k}'} V_{\mathbf{k},\mathbf{k}'}^{S} \Delta_{\mathbf{k}'}^{D}(\dots) = 0 \tag{III.48}$$

(see gap equation, it preserves the symmetry of the pair). A condensate with extended s-wave symmetry

$$\Delta_{\mathbf{k}}^{S} = \Delta_1 + \Delta_2(c_x + c_y) \tag{III.49}$$

vanishes when integrated with the d-wave part of the interaction. This means the two types of pairing are symmetry decoupled and moreover, the symmetry of the d-wave pair decouples against the local Coulomb pseudopotential. The quasiparticle energy for the d-wave condensate is:

> **What quasiparticle?**

$$E_{\mathbf{k}} = \sqrt{\epsilon_{\mathbf{k}}^2 + \Delta_{\mathbf{k}}^2(c_y - c_x)^2} \tag{III.50}$$
Figure III.1

It vanishes at intersections of nodes (where $\Delta_{\mathbf{k}} = 0$) and the Fermi surface (where $\epsilon_{\mathbf{k}} = 0$). At these points the dispersion can be linearized, they form Dirac cones of excitations with a relativistic dispersion . We can approximately solve the gap equation and get

$$\Delta_D(c_y - c_x) = \Delta_D(k_x^2 - k_y^2) = \Delta_0 \cos{(2\theta)} \tag{III.51}$$

The dependence $\Delta \propto \cos{(2\theta)}$ is typical for an $l = 2$ Cooper pair. The quasiparticle energy is then

$$E_{\mathbf{k}} = \sqrt{\epsilon_{\mathbf{k}}^2 + (\Delta_0 \cos{(2\theta)})^2} \tag{III.52}$$

The d-wave density of states does not have a clear gap, but instead a V-shaped structure. This linear DOS across the gap is due to the Dirac cones.

Margin notes:

What is the exact dispersion?

How exactly typical? $l = 2$?

Visualise that somehow?

How does the DOS compare with real materials? Do we have the V-shaped structure?

What exactly is shown in the fig
Figure III.2

IV Coherence length and penetration depth in strongly correlated superconductors

Order parameter (OP) of a superconducting condensate with FMP has the form

$$\Psi_{\mathbf{q}}(\mathbf{r}) = |\Psi_{\mathbf{q}}| e^{i\mathbf{q}\mathbf{r}} \qquad\qquad \text{(IV.1)}$$

where $\mathbf{q}$ is the center-of-mass momentum of Cooper pairs.

FMP is well known from Fulde-Ferrel-Larkin-Ovchinnikov (FFLO) theory, where the single-momentum phase used here corresponds to FF-type pairing.

IV.1 Ginzburg-Landau description

First: Motivate how the FMP constraint relates to λ_L and ξ_0.

GL low-order expansion of the free energy density f_{GL} in terms of the FMP-constrained OP reads

$$1 \qquad\qquad \text{(IV.2)}$$

The temperature dependent correlation length ξ appears as the natural length scale of the amplitude mode ($\propto \alpha$) and kinetic energy term

$$\xi(T) = \qquad\qquad \text{(IV.3)}$$

with the zero temperature value ξ_0 being the coherence length.
